

1. What is a class in Python, and how is it used to create objects?

A **class** in Python is a blueprint or template used to create objects. It defines the **attributes (data)** and **methods (functions)** that an object can have.

Example:

```
class Student:
    name = "ABC"
student1 = Student()
print(student1.name)
```

Here, Student is the class and student1 is an **object** created from the class.

2. What are methods and attributes in Python Classes?

- **Attributes:** Variables that store the data or properties of an object.
- **Methods:** Functions defined inside a class that perform actions or operations on the object.

Example:

```
class Student:
    name = "ABC"    # Attribute

    def display(self): # Method
        print(self.name)
```

```
student1 = Student()
student1.display()
```

Here, name is an **attribute** and display() is a **method**.
